Dear Dr. Vance,

Re: Ms. Sarah Miller

DOB: 22/04/1998

I am writing to request your assessment and specialist management of Ms. Miller, a 25-year-old primary school teacher, who has presented with features suggestive of severe acne and suspected rosacea.

Ms. Miller initially presented on 15/09/2023 with a six-month history of facial breakouts. She reported itchy, tight skin, for which she used OTC facial scrubs and washes without improvement. Initial management with topical Benzoyl peroxide was unsuccessful, causing burning sensation with increased redness and pustules. A subsequent trial of topical Clindamycin in October failed to improve the condition.

In November 2023, Ms. Miller was commenced on oral Lymecycline, 408 mg daily for refractory acne. At that time, she reported frequent facial flushing triggered by exercise and hot drinks. On examination, background erythema and telangiectasia were noted on the cheeks and nose; therefore, she was given advice on sun protection.

On today's visit, Ms. Miller's condition showed deterioration. Her examination showed severe cystic acne and evidence of scarring in addition to marked facial erythema and papulopustular lesions.

Ms. Miller's medical records show that she has a history of childhood eczema and seasonal hay fever. She does not smoke; however, she drinks one to two units of alcohol per week. She has a family history of adult acne in her mother.

I would be grateful if you could order further investigations for Ms Miller, if you find appropriate.

Should there be any queries, kindly do not hesitate to contact me.

Yours sincerely,

Doctor
