Dear Dr Jennings,

RE: Leo Bennett

DOB: 12/05/2016

I am writing to request urgent management and EEG for Leo, a 7-year-old boy who has presented with features suggestive of focal onset seizures, possibly Rolandic epilepsy.

Today, Leo experienced a third episode which was witnessed during the consultation. This event lasted ninety seconds and was characterized by rhythmic twitching of the right side of his mouth, speech arrest and profuse drooling. Although he remained conscious, he was mildly drowsy post-ictally. His neurological examination following the episode was normal.

Leo's symptoms initially started on 22/12/2023 with a thirty-second sensory episode involving tingling in his right hand while swimming without losing consciousness. His neurological examination was normal; therefore, he was advised to keep a diary.

On the following visit in the same month, Leo experienced facial drooping and speech arrest for one minute. He was reviewed in the Emergency Department at that time, where his assessment was unremarkable, and atypical migraine was suspected.

Leo is a well child, living with his parents with no significant medical history or prior head trauma. He has normal developmental milestones. He is not currently on any regular medications. Please note, his maternal uncle has well-controlled epilepsy.

I would be grateful if you could assess Leo at your earliest convenience. Should there be any queries, kindly do not hesitate to contact me.

Yours sincerely,

Doctor
