Dear Dr Jenkins,

RE: Mr Liam Sterling

DOB: 15/11/1982

I am writing to update you on Mr Sterling who is being discharged today from our hospital into your care following uncomplicated laparoscopic cholecystectomy for acute cholecystitis. Your follow-up and ongoing care would be highly appreciated.

Mr Sterling was admitted on 05/01/2024 with a ten-hour history of severe, colicky, right upper quadrant pain radiating to the right shoulder blade, which was associated with nausea and vomiting. Clinical examination revealed right upper quadrant tenderness, a temperature of 38.3°C and positive Murphy's sign. An ultrasound scan confirmed the diagnosis of acute cholecystitis, showing multiple gallstones, a thickened gallbladder wall, and pericholecystic fluid.

Mr Sterling underwent an uncomplicated surgical procedure the following day. His postoperative recovery was initially unremarkable, and he was commenced on oral fluids and advised to mobilize with assistance.

Today, Mr Sterling reported an itchy and tight sensation in the umbilical area. This was evidenced by mild erythema, localized swelling, clear discharge and a temperature of 37.5°C; however, other port sites were healing well. His examination showed soft, slightly bloated abdomen. Subsequently, he was diagnosed with surgical site infection. Management has been initiated with a seven-day course of oral Clindamycin, 300 mg four times a day due to his penicillin allergy in addition to wound dressing.

It would be appreciated if you could review Mr Sterling's wound in five days and remove his non-dissolvable sutures. Please note, he has been advised to avoid heavy lifting and long-distance cycling for six weeks.

Should there be any queries, please do not hesitate to contact me.

Yours sincerely,

Surgical Registrar

OET with Dr. Ahmed Hesham
